

Morals Matter, But Not For Everyone*

The Conditionality of Moral Foundations in Political Reasoning

Patrick W. Kraft[†]

October 21, 2016

Abstract

Moral Foundations Theory (MFT) proposes that political attitudes and ideology are structured by fundamental moral intuitions. While there is growing empirical support for the theory in the social sciences, recent studies have questioned the notion that moral intuitions can be viewed as stable traits. The present paper contributes to the literature by introducing an alternative measurement approach to explore the conditions under which individuals express moral considerations when discussing their political preferences. Specifically, we identify references to moral intuitions in open-ended responses using a Moral Foundations dictionary. The reliance on moral foundations in political reasoning is largely consistent with MFT, but whether and how individuals evoke moral considerations is conditional on their political knowledge and exposure to political discourse. Moral foundations have a powerful influence on public opinion and political behavior but this relationship is most evident among the politically knowledgeable—implying that moral reasoning is as much learned from the political world as it is innate.

Keywords: Moral Foundations Theory, Political Reasoning, Ideology, Open-ended Survey Responses

*An earlier version of this paper was presented at the 73rd Annual Conference of the Midwest Political Science Association, April 16-19, 2015. The manuscript and code are available on GitHub: <https://github.com/pwkraft/mft>.

[†]Ph.D. Candidate, Stony Brook University, patrick.kraft@stonybrook.edu.

To what extent do the public’s political beliefs have a meaningful structure? This question has been of frequent scholarly interest in political science and related disciplines, yielding an array of different perspectives. Early accounts emphasized how ordinary citizens lack consistent political attitudes and knowledge necessary to form meaningful ideologies (Converse, 1964). However, with increasing levels of polarization and partisan sorting in contemporary politics (e.g. Mason, 2015), there has been renewed interest in systematic psychological and attitudinal differences between liberals and conservatives (Jost, 2006). One such area of research focuses on the differing moral concerns of liberals and conservatives. According to *Moral Foundations Theory* (MFT), moral thinking is organized by five innate intuitions: harm/care, fairness/reciprocity, ingroup/loyalty, authority/respect, and purity/sanctity (Haidt and Joseph, 2008; Graham et al., 2011). Liberals and conservatives differ in their relative emphasis of these foundations, with liberals prioritizing the foundations of harm/care and fairness/reciprocity, and conservatives endorsing all five dimensions more or less equally (Graham, Haidt, and Nosek, 2009).¹

A series of studies builds on MFT and provides evidence for the influence of moral foundations on issue preferences (Koleva et al., 2012; Kertzer et al., 2014; Low and Wui, 2015; Clifford, Jerit, Rainey, and Motyl, 2015), candidate trait evaluations (Clifford, 2014), and vote choice (Iyer et al., 2010; Franks and Scherr, 2015). However, recent research cast some doubt on the theory’s basic tenets (e.g., Suhler and Churchland, 2011). Smith et al. (2016) empirically investigated three implicit assumptions underlying MFT, namely that moral foundations are individual traits that are relatively stable over time, that changes in moral foundations predict changes in political ideology, and that the foundations are heritable. The empirical evidence provided by Smith et al. (2016) does not support these assumptions, but this critique stands in contrast to the growing body of work that documents the political relevance of moral foundations. The present study attempts to reconcile this contradiction

¹Subsequent accounts of MFT discussed the inclusion of further dimensions, such as *Liberty/Oppression* (c.f., Graham et al., 2013; Haidt, 2012). However, the analyses presented here will only focus on the dimensions initially suggested in Haidt and Joseph (2008).

by taking a different tack and directly examining the conditions under which the moral foundations are consequential to a person’s political judgments. Indeed, [Smith et al. \(2016\)](#) conclude that their findings are “consistent with the notion of moral foundations being highly responsive to context: more of a state than a trait.” Yet, few studies systematically investigated the conditionality of the relationship between moral foundations and political attitudes (see [Clifford, Jerit, Rainey, and Motyl, 2015](#), for a notable exception).

The present study provides a first step in this direction by directly analyzing the degree to which individuals vary in the expression of moral concerns in political reasoning and judgment. Using data from the 2012 American National Election Study, we create a measure of moral reasoning based on individual responses to the open-ended likes-dislikes questions and the moral dictionary introduced by [Graham, Haidt, and Nosek \(2009\)](#). Relying on open-ended questions rather than traditional survey-based measures of moral foundations allows us to investigate patterns of moral reasoning among individuals where the potential connection between morality and politics is not induced or facilitated by design.

The analyses reveal systematic differences between liberals and conservatives in their reliance on specific moral considerations when evaluating political parties and candidates even without being cued to think about morality. These differences, in turn, affect political evaluations as well as voting behavior—even after controlling for a person’s party identification. Most importantly, the overall reliance on moral foundations in political judgment as well as the respective differences between liberals and conservatives are conditional on knowledge and exposure to political discourse. Even though the ideological differences are broadly consistent with MFT, moral reasoning in the realm of politics is more context-specific than previous research suggests. From a methodological standpoint, the present study showcases techniques to improve the analysis of open-ended survey responses and illustrates how these data can be used to investigate the determinants of political reasoning.

Moral Foundations Theory

Moral values serve as a source for coherence in political attitudes and they shape individual belief systems. As such, one major focus of the moral foundations framework is the relationship between moral values and political belief systems (c.f., [Haidt, 2012](#)). Liberal morals have been shown to focus on “individualizing” foundations, which include harm/care and fairness/reciprocity. Conservatives, on the other hand, also emphasize the remaining foundations of ingroup/loyalty, authority/respect, and purity/sanctity, labeled the “binding” foundations ([Haidt and Graham, 2007](#); [Graham, Haidt, and Nosek, 2009](#)). Haidt and colleagues developed the Moral Foundations Questionnaire (MFQ) to measure individual differences in the emphasis of each foundation. The MFQ consists of a series of items that explicitly ask people to rate the relevance of different considerations when making decisions about right and wrong. The questionnaire also asks individuals to indicate their level of agreement with statements that represent the values implied by the five foundations.

Relying on the MFQ, subsequent research extended the initial findings. For example, scholars showed that moral concerns predicted attitudes towards a wide variety of divisive political issues (e.g. [Koleva et al., 2012](#); [Kertzer et al., 2014](#); [Low and Wui, 2015](#)). [Federico et al. \(2013\)](#) linked moral foundations to individual social dominance orientation (SDO) and right-wing authoritarianism (RWA). Further research directly investigated the relationship between moral foundations and candidate preferences ([Iyer et al., 2010](#)) or trait inferences about candidates ([Clifford, 2014](#)). Moral foundations have also been shown to predict turnout ([Johnson et al., 2014](#)) as well as voting behavior in the 2012 US Presidential election ([Franks and Scherr, 2015](#)). Overall, this research strongly supports the view that liberals and conservatives endorse different moral foundations and that these differences are related to political attitudes, evaluations, and behavior.

[Smith et al. \(2016\)](#), on the other hand, used the MFQ to examine some basic assumptions underlying MFT using data from several twin panels. The authors investigated whether moral foundations can be viewed as stable traits that vary little over time, whether changes

in moral foundations predict changes in ideology (or vice versa), and whether there are sufficient signs of heritability in the emphasis of moral foundations. Overall, the evidence reported in [Smith et al. \(2016\)](#) seems to contradict MFT: the foundations are less stable than ideology, do not seem to predict changes in the latter over time, and do not seem to be inherited through genes. However, the analyses presented by [Smith et al. \(2016\)](#) are not without limitations. For example, their analyses of stability over time relied on different subscales of the MFQ in each of the waves, which might induce some of the instability between waves in the sample. Nevertheless, the results raise the possibility that the relationship between ideology and moral foundations might not be as stable as initial research suggested.

In order to reconcile the divide between the growing body of research highlighting the influence of the MFT on political attitudes and work challenging those conclusions, we need to directly investigate the conditions under which moral reasoning occurs when people think about politics. As we will argue below, this step involves measuring moral foundations in political reasoning without relying on the MFQ, which has been used in nearly all existing work (but see [Clifford, 2014](#)).

The ‘Missing Link’ to Political Reasoning

Previous research has relied almost exclusively on MFQ, which explicitly asks people to judge the relevance of particular moral considerations (e.g. [Graham et al., 2011](#)). However, by directly asking people about the importance of considerations related to the five foundations, previous analyses presuppose an important link that requires more careful empirical investigation. More specifically, it does not allow us to directly examine the conditions under which the connection between moral values and political ideology manifests itself when citizens reason about politics and evaluate political actors. Measuring moral foundations using the MFQ therefore imposes constraints on our theoretical conceptualization of moral reasoning and the range of hypotheses we can investigate. Some scholars have criticized the

MFQ because it does not ask people to make moral judgments per se (e.g. Clifford, Iyengar, Cabeza, and Sinnott-Armstrong, 2015). Indeed, Graham, Haidt, and Nosek (2009, 1031) describe the reports on moral relevance as “self-theories of moral judgment,” rather than direct measures of judgment itself. Such abstract self-theories might, in turn, deviate from actual judgments in specific situations.

From a theoretical perspective, moral foundations are viewed as stable traits that affect attitudes and preferences regardless of potential individual differences and contextual effects. However, the incorporation of moral considerations in a specific political context could be much more variable. Previous research suggests that campaigns and elite communication can have important influences on individual moral reasoning. For example, Clifford and Jerit (2013) found that at the elite level, proponents and opponents of stem cell research place distinctive weights on moral foundations which in turn affected the public attitudes and the underlying considerations related to the issue. A subsequent study showed that elite rhetoric plays an important role in linking individual moral foundations with political attitudes, but only for those individuals who were most likely be exposed to it (Clifford, Jerit, Rainey, and Motyl 2015; also see Day et al. 2014). While these studies do not contradict MFT, they cast some doubt on the notion that moral reasoning in politics is as a direct reflection of stable moral intuitions.

The literature on *moral convictions* further suggests that moral reasoning in the realm of politics can be more variable than proposed by MFT. Skitka and colleagues argue that individuals hold moralized attitudes if they have a universal perception of “right and wrong” connected to the issue at hand (Skitka, Bauman, and Sargis, 2005; Mullen and Skitka, 2006; Skitka, 2010). This view implies that there can be considerable variance in the degree to which moral considerations are raised between individuals and across issues. However, the MFQ measures moral foundations as general traits that are implicitly assumed to apply in any context.

The present study addresses this gap by examining whether people utilize the foundations

in their day-to-day political reasoning (i.e., without being prompted by the language of a questionnaire). Moving beyond the MFQ and measuring moral reasoning as the explicit expression of foundations allows us to directly examine the degree to which political attitudes are infused by moral convictions. As such, we investigate whether differences in moral reasoning between liberals and conservatives manifest themselves in a more unobtrusive context.

Insofar as moral intuitions play a role in political reasoning, citizens should rely on the moral foundations when reporting their attitudes towards political actors, even if they are not explicitly asked to do so. Thus, the first step of the analyses will be to replicate the findings connected to MFT and ideology using open-ended survey responses to general questions about political preferences. We expect that liberals will be more likely to spontaneously mention the moral foundations of harm/care and fairness/reciprocity than conservatives when evaluating political parties and candidates. Conversely, conservatives will be more likely to emphasize moral foundations of ingroup/loyalty, authority/respect, and purity/sanctity than liberals. Moral reasoning measured through open-ended responses is further expected to be politically consequential. The differences in the degree to which each foundation is emphasized should directly affect political preferences and vote choice consistent with the propositions of MFT.

After replicating the basic findings in the MFT literature in a more unobtrusive survey context that does not evoke issues of morality, the present study contributes to the literature by clarifying the conditionality of the foundations in day-to-day reasoning. Individuals who are exposed to the political process and resulting elite communications are expected to be more likely to incorporate moral considerations in their political reasoning because they adopt the respective arguments from elite discourse. Individuals who are not engaged in politics, on the other hand, might focus on other considerations when forming their preferences. The extent to which individuals rely on moral considerations when evaluating political actors is therefore not necessarily stable among individuals and across contexts. Rather, the

tendency to emphasize moral foundations may be contingent upon individual levels of political knowledge, media exposure and political discussions. We expect that individuals who are more exposed to political discourse and more engaged in politics will be more likely to emphasize moral foundations when evaluating political parties and candidates than those who have less experience and are less politically engaged. Furthermore, these differences are expected to exacerbate the ideological divide in moral reasoning.

The degree to which political attitudes are moralized as well as the ideological differences in moral reasoning cannot be investigated by relying solely on the MFQ. Instead, it is necessary to differentiate between a person’s tendency to endorse a moral *foundation* (as a stable trait, measured by MFQ), and moral *reasoning* as the actual reliance on specific moral considerations and arguments in specific political judgments. Previous research has largely neglected this difference.

Measuring Moral Reasoning in Open-Ended Responses

The present study is the first to explicitly focus on moral *reasoning* by analyzing individual verbatim expressions of political attitudes and preferences. We identify references to specific moral considerations when respondents discuss aspects that they like and dislike about political parties and candidates using the moral foundations dictionary created by [Graham, Haidt, and Nosek \(2009\)](#). While the dictionary was initially used to analyze the content of liberal and conservative sermons, it was developed as a collection of general associations related to each foundation that could be applied in any context.² For example, terms like “protect” and “suffer” indicate references to the harm/care foundation, “equality” and “tolerant” signal reasoning based on the fairness/reciprocity foundation, “patriot” and “betrayal” indicate reference to the ingroup/loyalty foundation, “honor” and “respect” signal considerations related to authority/respect, whereas “integrity” and “duty” indicate reference to the purity/sanctity foundation. Other studies in the domain of MFT relied

²See Appendix A for the full content of the dictionary.

on (variations of) the dictionary to investigate moral considerations in elite communication (e.g. in news media coverage about stem cell research, c.f., [Clifford and Jerit, 2013](#)), but no research to date examined individual political reasoning in open-ended survey responses.

Based on the terms signaling each foundation, we can create MFT scores for any text document. Conventional dictionary-based methods consist of the proportion of signal word occurrences in each document (e.g. [Graham, Haidt, and Nosek, 2009](#)):

$$\text{MFT}_{if} = \frac{1}{W_i} \sum_{t \in \mathcal{D}_f} w_{it}, \quad (1)$$

where MFT_{if} denotes the score of document i for foundation f , W_i is the total number of words in document i , t indicates a term in the set of signal terms of foundation dictionary \mathcal{D}_f , and w_{it} denotes the number of occurrences of term t in document i . As such, a document’s MFT score for each foundation is the overall proportion of words in the document that signal the respective foundation.

However, this conventional approach comes with an important drawback. While [Graham, Haidt, and Nosek \(2009\)](#) conceived the dictionary as applicable across contexts, some terms might be problematic when applied to verbatim likes/dislikes responses. In particular, when respondents describe their attitudes towards political actors, certain words might be too ubiquitous to be regarded as an unambiguous indicator for specific moral considerations. For example, the moral foundations dictionary includes “leader” and “honor” as signal words for the authority/respect dimension. Should both words be considered as equally indicative of the respective foundation? After all, if respondents describe their attitudes towards presidential candidates, they might be inclined to describe their qualities as *leaders* irrespective of explicit moral considerations related to authority.

One way to address this problem using conventional methods would be to revise the dictionary and eliminate words that are deemed problematic. However, this leaves a lot of discretion to the researcher. Drawing on techniques developed in the field of information

retrieval, we propose an alternative approach. If it is the case that “leader” represents a term that is commonly used to describe presidential candidates (irrespective of moral considerations), then we would expect that it should appear more frequently in open-ended responses across all individuals. Terms that are used by a large majority of respondent provide less information about differences in their (moral) reasoning than terms that only occur in few responses. Accordingly, to calculate the MFT score for a foundation, we weight each term in the dictionary according to its ubiquity across documents, which serves as a proxy for the term’s discriminative information (c.f. for example [Manning et al., 2008](#)):

$$\text{MFT}_{if} = \frac{1}{W_i} \sum_{t \in \mathcal{D}_f} \left[w_{it} * \log_{10} \left(\frac{N}{n_t + 1} \right) \right], \quad (2)$$

where N denotes the total number of documents, and n_t is the number of documents in which the term t appears. The weight w_{it} represents the inverse of the proportion of documents in which the target term appears.³ As such, terms that are ubiquitous across the entire corpus receive a lower weight, and terms that only appear in few documents receive a higher weight. We add +1 to the denominator in order to ensure that it does not equal zero if a dictionary term does not appear in any of the documents.

The MFT score is a continuous measure that has a lower bound of 0 (document does not contain any dictionary terms) and is independent of document length (since it is based on relative occurrences). Higher scores imply larger proportions of dictionary terms in a document. Most importantly, however, words that appear in nearly all open-ended remarks affect MFT scores less than the words mentioned only by few respondents because ubiquitous words convey less information about differences across individuals. Overall, the MFT score provides a correction for potential distortions due to suboptimal terms in the dictionary while leaving its exact content outside of the researcher’s discretion. Since the MFT score’s

³This specification is usually referred to as tf-idf weighting and is commonly used in quantitative text analyses. The acronym tf-idf stands for “term frequency - inverse document frequency,” which refers to the rationale that the frequency of specific terms are weighted by the inverse of the frequency of occurrence across documents. See [Manning et al. \(2008, ch. 6\)](#) for an introduction.

nominal values above zero do not have a substantive interpretation, they are rescaled to unit variance.

Data, Variables, and Model Specification

The analyses presented henceforth are based on the 2012 American National Election Study, which contains two representative cross-sectional samples. One sample was conducted by computer assisted face-to-face interviews while the other sample is based on an internet panel group. Both samples are pooled in the analyses. While each consisted of a pre-election and a post-election wave, most items described below are drawn from the pre-election wave.⁴

The major dependent variables (i.e., the MFT scores described above) are based on open-ended questions in which respondents were asked to report what they *liked* and *disliked* about either presidential candidate as well as the Republican and Democratic parties. More specifically, respondents were asked to list anything in particular that they like/dislike about the Democratic/Republican party as well as anything that might make them vote/not vote for either of the Presidential candidates and were probed by the interviewer asking “anything else?” until the respondent answered no. The responses to the eight open-ended like/dislike questions (evaluating both parties and both candidates) were aggregated for each individual and pre-processed by correcting spelling errors using an implementation of the Aspell spell checking algorithm in R (www.aspell.net).

Respondents were not included in the analysis if they failed to provide an answer to all open-ended items, or if the interview language was Spanish. Table B.1 in the appendix provides an overview over the number of omitted cases. About 4% of the interviews were held in Spanish and about 7% of the respondents did not provide any open-ended response. Furthermore, Figure B.1 in the appendix displays histograms of the length of the respondents’ answers to all open-ended items. On average, the collection of all open-ended responses

⁴The open-ended items were included only in the pre-election wave. Accordingly, wherever possible, the set of explanatory variables was limited to the pre-election wave.

consists of about 75 words for each individual.

Due to the fact that the MFT scores are bound at zero (i.e. none of the words in the dictionary appear in the response), individual response patterns are modeled via Tobit regressions for each of the moral foundations under consideration. The Tobit framework allows us to decompose the estimates into the effect on the probability of mentioning a specific foundation *at all* as well as the degree of emphasis on the foundation given that it was mentioned by a respondent (see McDonald and Moffitt, 1980, for details on the decomposition of Tobit model estimates).

The key independent variable used to predict the emphasis on each of the moral foundations, is *political ideology*. Respondents were asked to place themselves on a seven-point scale ranging from extremely liberal to extremely conservative, which was transformed into dichotomous indicators for respondents who identified as liberals, conservatives, or moderates. Additional control variables included in the analyses are *church attendance*, *education* (college degree), *age*, *sex*, *race* (African American), survey mode (online vs. offline), as well as the overall length of the individual responses in the open-ended questions (*measured as logged number of words*). Furthermore, the 2012 ANES included the *Wordsum* vocabulary test as a measure of literacy and verbal skill. It consists of a series of items asking respondents to choose a term that is closest to a target word. The Wordsum score consists of an additive index of correct responses in ten individual trials. The inclusion of the length of individual responses and the Wordsum score as control variables should account for potential confounding factors such as general effects of increased political literacy on the complexity of open-ended responses.

In order to examine the relevance and consequences of moral reasoning measured through open-ended responses, the MFT scores for each of the moral foundations are used as independent variables to predict political outcomes. The dependent variables considered here are *candidate* and *party evaluations* (measured as the respective feeling thermometer differentials), as well as *voting behavior* (measured as a dichotomous indicator of vote choice for the

Democratic rather than the Republican Presidential candidate reported in the post-election wave). In addition to the controls discussed previously, these analyses include measures of *party identification*, which were recoded similarly to ideology.

The next set of analyses investigates whether the expression of moral considerations in political judgment is conditional on knowledge and exposure to political discourse. The factors that are therefore expected to be related to references to moral foundations include *political knowledge*, which was measured as the sum of correct answers to factual knowledge questions. The analyses also investigate the effect of *political media exposure* and the frequency of *political discussions* with friends and family members. Here, we not only look at the influence on individual foundations, but also examine whether these factors influence *general* moral reasoning. This latter variable is measured as the sum of individual MFT scores across all dimensions (rescaled to unit variance after summation), which can be interpreted as a aggregate measure of how much respondents emphasize any moral consideration in their responses. Whenever appropriate, independent variables were rescaled to range from 0 to 1. Figure B.2 in the appendix provides histograms of all independent variables included in different stages of the analyses.

Ideological Differences in Moral Reasoning

Figure 1 provides a first descriptive overview of moral reasoning in open-ended responses. The figure displays the proportion of respondents who mentioned words that were included in the five different moral foundations dictionaries as well as their 95% confidence intervals.⁵ Since responses for each individual represent their likes and dislikes across all eight open-ended items, each proportion indicates the percentage of individuals who mentioned a signal word belonging to the respective moral foundation in any of his or her open-ended responses evaluating the parties or candidates.

⁵Note that the proportions are based on the subset of the sample that provided a response to at least one of the open-ended items, and for which the interview was held in English.

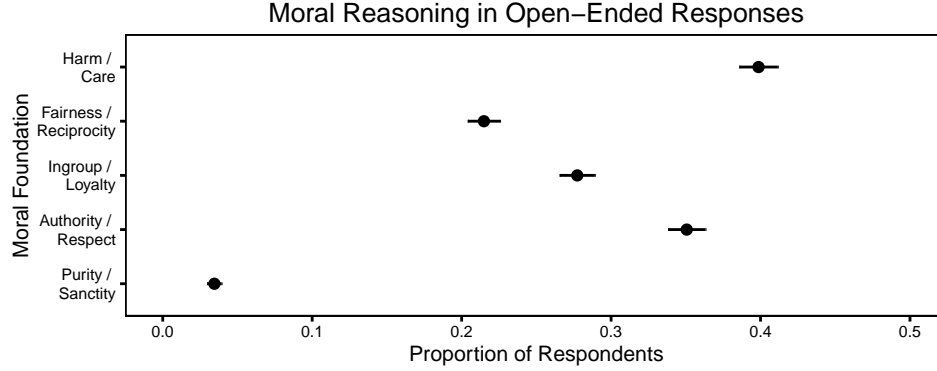

Figure 1: Proportion of respondents mentioning each of the moral foundations in any of their open-ended responses, along with 95% confidence intervals. The first two foundations are often labeled individualizing foundations, which have been shown to be more prevalent among liberals, while the remaining ones are described as binding foundations, which are more prevalent among conservatives.

The moral foundation most frequently mentioned is harm/care: About 40% of the respondents mentioned at least one word included in respective dictionary. The second most frequently mentioned moral foundation is authority/respect with about 35%. The proportion of respondents emphasizing ingroup/respect or fairness reciprocity is slightly lower with about 28% and 22%, respectively. Purity/sanctity, on the other hand, was almost never mentioned by any of the respondents. This finding is surprising, since other studies found the foundation to be an important predictor of divisive political attitudes (Koleva et al., 2012). This result suggests that the terms contained in the purity/sanctity dictionary might be too uncommon in the context of politics and therefore not relevant for attitude expression. Due to the very rare mentioning of the purity/sanctity dimension, the subsequent analyses will concentrate on the remaining four moral foundations.⁶ Subsequent analyses focusing on the dimension of purity/sanctity in open-ended survey responses might necessitate a revision of the moral foundation dictionary.

Overall, Figure 1 shows that a substantial proportion of individuals evokes moral con-

⁶Unfortunately, this issue cannot not be properly addressed by relying on tf-idf cosine scores. The weighting can correct for some distortions due to individual ubiquitous terms in the dictionaries, but it cannot compensate for the fact that the purity dictionary as a whole contains mostly words that are never mentioned by respondents.

siderations when describing their political attitudes even when they are not explicitly asked about morality. However, we are ultimately interested in ideological differences in the emphasis of moral foundations in open-ended responses. As such, we now turn to a more in-depth analysis of the MFT scores as measures of moral reasoning.

We begin by estimating a set of Tobit regressions using ideology (and the control variables discussed above) to predict the individual MFT score for each of the moral foundations (excluding purity/sanctity).⁷ To reiterate, the MFT score measures the overlap between individual open-ended responses and the dictionaries for each foundation and has a value of 0 if none of the words in a dictionary appear in a response. Figure 2 compares liberals and conservatives while holding all other variables constant at their respective means. The effects of ideology (liberal - conservative) estimated in the Tobit model are decomposed into two parts: the left panel displays the change in probability of the MFT score to be larger than zero (i.e. the probability of mentioning a specific foundation at all), whereas the right panel displays the expected change in the MFT score given that it is larger than zero (i.e. the degree of emphasis on a foundation given that it was mentioned, measured in standard deviations).

Positive values denote a higher probability of mentioning the respective moral foundation (left panel) or a higher MFT score (right panel) of a response among individuals who identified as liberals, while negative values indicate a higher probability/higher score among conservatives. The effects are consistent with the expectations of MFT for three out of four moral foundations. Liberals are significantly more likely to mention the foundations of harm/care and fairness/reciprocity. For respondents who identified as liberal as compared to conservative, the probability of referencing these two foundations is increased by about 9%. Furthermore, given that respondents mention these two foundations at all, liberals emphasize it more than conservatives when evaluating political parties and candidates. The MFT score for the harm/care foundation is about 0.1 standard deviations higher among liberals

⁷The full estimates for this and all subsequent models discussed the remainder of the paper are presented in Appendix E.

Figure 2: Difference between liberals and conservatives in the probability of mentioning each moral foundation (left panel), and in the MFT score given that the foundation was mentioned (right panel), holding all other control variables at their respective means (along with 95% confidence intervals). Positive values indicate that liberals are more likely to mention the respective foundation than conservatives (left panel), or emphasize it more than conservatives (right panel), and vice versa. Estimates are based on separate Tobit models for each foundation’s MFT score. The dimension of purity/sanctity was omitted due to its low general prevalence in individual attitude expressions (c.f., Figure 1).

than conservatives. The effect is slightly larger for the fairness/reciprocity dimension. Conversely, being conservative increases the MFT score for the foundation of ingroup/loyalty by about 0.1 standard deviations. For the authority/respect dimension, we do not observe any significant differences between liberals and conservatives.

Taken together, the results are largely consistent with previous findings in the literature on MFT. Individuals evoke moral considerations when evaluating political parties and candidates without being explicitly asked about morality. Furthermore, there are systematic differences between liberals and conservatives in their reliance on binding and individualizing foundations (see [McAdams et al., 2008](#), for similar ideological differences when analyzing the content of life-narrative interviews). However, the fact that the authority/respect foundation showed insignificant patterns could suggest that the public’s reliance on moral foundations may be more context-specific than previously thought.

The Political Relevance of Moral Reasoning

A skeptical reader might argue that even if the ideological patterns are consistent with MFT, the expression of moral considerations might not be as strongly related to other forms of political behavior as latent moral foundations measured by the MFQ. In order to alleviate this concern, we proceed to show that the expression of specific moral foundations in open-ended responses has important effects on political attitudes and behavior that match existing findings in the literature. Previous research relying on the MFQ has linked moral foundations to an array of political outcomes, such as candidate preferences (Iyer et al., 2010) and voting behavior (Franks and Scherr, 2015). Do we see the same patterns for explicit moral reasoning as compared to latent moral foundations?

Figure 3: Change in predicted feeling thermometer differential when MFT score is increased from its minimum (no overlap between dictionary and response) by one standard deviation, holding all other control variables constant at their respective means (along with 95% confidence intervals). Positive values indicate that respondents who emphasized the respective foundation evaluated the Democratic candidate/party more favorably than the Republican candidate/party, and vice versa. Estimates are based on a single OLS model (using robust standard errors) including MFT scores for each foundation and gray triangles indicate estimates while additionally controlling for party identification. The dimension of purity/sanctity was omitted due to its low general prevalence in individual attitude expressions (c.f., Figure 1).

As a first step, we examine the relationship of moral reasoning and attitudes towards political parties and candidates. Figure 3 presents OLS estimates where feeling thermometer differentials between the Republican and the Democratic party (left panel) and between both Presidential candidates (right panel) are regressed on MFT scores for all moral foundations (including the control variables discussed above). Positive values indicate more favorable evaluations for the Democratic candidate or party and negative values indicate more favorable evaluations of the Republican candidate or party. The patterns are largely consistent with the previous results on ideological differences. Individuals who emphasize considerations related to harm/care, and fairness/reciprocity evaluate the Democratic party/candidate on average about 3 points higher than the Republican party/candidate (on a 100 point scale). On the other hand, if individuals emphasized the ingroup/loyalty dimension, they reported stronger preferences for the Republican party/candidate. These effects are robust after controlling for individual party identification. Thus, in both analyses in Figure 3, we observe sizable and significant effects for the influence of moral reasoning.

Figure 4 presents the changes in expected probabilities of voting for the Democratic (vs. the Republican) presidential candidate in the 2012 election for individuals emphasizing the moral foundations in their open-ended responses. The estimated probabilities are based on logit models including MFT scores for each moral foundation as independent variables (as well as the remaining controls), which were held constant at their mean values when computing expected values. Again, the patterns are strikingly similar to the results presented thus far, and largely consistent with MFT. Individuals who emphasized moral considerations related to the harm/care and fairness/reciprocity foundations are more likely to vote for Barack Obama than for Mitt Romney. Respondents who emphasized the ingroup/loyalty foundation, on the other hand, were less likely to vote for Obama.

The effects on political evaluations and vote choice might not seem large, but bear in mind that the measure of moral reasoning is based solely on the content of open-ended responses in which respondents were *not* explicitly asked about morality. Yet, the moral considerations

Figure 4: Change in predicted probabilities to vote for Democratic candidate when MFT score is increased from its minimum (no overlap between dictionary and response) by one standard deviation, holding all other control variables constant at their respective means (along with 95% confidence intervals). Positive values indicate that respondents who emphasize the respective foundation are more likely to vote for the Democratic candidate, and vice versa. Estimates are based on a single logit model including MFT scores or each foundation and dotted lines indicate estimates while additionally controlling for party identification. The dimension of purity/sanctity was omitted due to its low general prevalence in individual attitude expressions (c.f., Figure 1).

evoked by respondents were powerfully related to party and candidate evaluations as well as vote choice, even after controlling for strength of party identification and the length of individual responses. Overall, the analyses show that people’s open-ended comments about both candidates and both parties are imbued with moral content and that these comments relate to political judgments in the manner predicted by MFT.

The Conditionality of Moral Reasoning

Having shown that liberals and conservatives differ with regard to the moral foundations they emphasize when evaluating political actors and that these differences allow us to predict preferences and vote choice, we now investigate whether the reliance on moral considerations varies between individuals as a product of political knowledge and exposure to political discourse. Campaign exposure and discussions influence the degree to which political attitudes

are moralized to the extent that individuals adopt moral rhetoric from elites and their peers. As such, we first focus on determinants of the general tendency to emphasize *any* moral foundation by regressing the sum of MFT scores for each individual on political knowledge, political media exposure, and frequency of political discussions. Figure 5 depicts the respective effects when each independent variable is increased from its empirical minimum value to its empirical maximum value, holding all other variables constant at their means. Again, estimates are based on tobit models that take into account the censoring of the moral reasoning measure and effects are decomposed into the probability of mentioning any moral foundation (left panel) as well as the emphasis on morality, given that any foundation was mentioned (right panel).

Figure 5: Change in predicted overall reliance on moral foundations depending on political knowledge, media exposure, and frequency of political discussions. The plot shows differences in predicted probabilities of mentioning any moral foundation (left panel) as well as in the summed MFT scores given that any foundation was mentioned (right panel), if each of the independent variables is increased from its minimum to its maximum value holding all other variables constant at their respective means (along with 95% confidence intervals). Positive values indicate higher probability of mentioning, or stronger emphasis on moral foundations. Estimates are based on Tobit models and gray triangles indicate estimates while additionally controlling for the remaining variables presented in the figure. The dimension of purity/sanctity was omitted due to its low general prevalence in individual attitude expressions (c.f., Figure 1).

All variables considered here have a positive effect on the individual likelihood to mention as well as the respective emphasis on moral foundations when evaluating political parties and candidates. Higher political knowledge, higher exposure to political media and news, as well as more frequent political discussions increase the degree to which individuals rely on moral considerations. Thus, citizens *learn* to embed moral reasoning in their political evaluations. While moral intuitions themselves might well be innate, the extent to which individuals make use of these intuitions when thinking about politics and evaluating political actors is context-dependent and subject to individual heterogeneity.

The significant positive effect of frequent political discussions (even after controlling for political knowledge and media exposure), is especially interesting. Citizens who engage in frequent political arguments are more likely to use moral considerations when evaluating candidates and parties. This result suggests that morality serves as a rhetorical tool utilized to convince others of certain political views.⁸

Beyond their effects on *general* moral reasoning, we want to investigate whether the effects of political knowledge, media exposure, and discussions influence the systematic differences between liberals and conservatives in the emphasis on *specific* dimensions. Consider again the results presented in Figure 2, which showed that liberals were more likely to emphasize the harm/care and fairness/reciprocity dimensions, while conservatives were more likely to emphasize the ingroup/loyalty foundation. In order to investigate whether the differences are conditional on political knowledge, media exposure, and discussions, we extend the original models by including interaction terms for each of the three variables that have been shown to influence the overall reliance on moral considerations. Based on these models, we can examine whether political knowledge, media exposure, and discussion frequency exacerbate the ideological divide in moral reasoning.

⁸This conclusion is also supported by the finding that the reliance on moral considerations is more pronounced among individuals who engage in non-conventional forms of participation (signing petitions, wearing campaign buttons, writing letters to representatives). On the other hand, simply participating in the previous election did not increase the emphasis of moral foundations significantly. These results are presented in the appendix, Figure D.1.

Figure 6: Difference between liberals and conservatives in the probability of mentioning each moral foundation (left panel), and in the MFT score given that the foundation was mentioned (right panel), comparing individuals with low and high levels of political knowledge while holding all other control variables at their respective means (along with 95% confidence intervals). Positive values indicate that liberals are more likely to mention the respective foundation than conservatives (left panel), or emphasize it more than conservatives (right panel), and vice versa. Estimates are based on separate Tobit models for each foundation’s MFT score where ideology is interacted with political knowledge. The dimension of purity/sanctity was omitted due to its low general prevalence in individual attitude expressions (c.f., Figure 1).

Figure 6 displays the analyses equivalent to the previous results in Figure 2, now differentiating between individuals with high and low levels of political knowledge. While we can observe the same systematic differences between liberals and conservatives for individuals with high levels of political knowledge (upper panels), the effects of ideology disappear among individuals with low levels of political knowledge (lower panels) for all foundations except fairness/reciprocity. As such, we recover systematic differences in moral reasoning between liberals and conservatives only among the sub-group of highly knowledgeable respondents. It is worth noting again that all models presented here control for education, logged overall response length, and the Wordsum score, which should account for potential confounding factors related to the respondents’ eloquence when discussing their political attitudes. Of course, not all changes from significant to insignificant effects are themselves necessarily sig-

nificant (c.f., Gelman and Stern, 2006). Figure D.2 in the appendix provides detailed results on the statistical significance of the difference-in-differences between the comparisons for this and the following analyses. In the case of political knowledge, we see that especially the ideological divide on the harm/care dimension is significantly larger among individuals with high political knowledge.

Figure 7: Difference between liberals and conservatives in the probability of mentioning each moral foundation (left panel), and in the MFT score given that the foundation was mentioned (right panel), comparing individuals with low and high levels of political media exposure while holding all other control variables at their respective means (along with 95% confidence intervals). Positive values indicate that liberals are more likely to mention the respective foundation than conservatives (left panel), or emphasize it more than conservatives (right panel), and vice versa. Estimates are based on separate Tobit models for each foundation’s MFT score where ideology is interacted with political media exposure. The dimension of purity/sanctity was omitted due to its low general prevalence in individual attitude expressions (c.f., Figure 1).

Next, we turn to a parallel analysis focusing on the influence of political media exposure instead of political knowledge. Figure 7 compares the ideological differences for individuals with high and low levels of media exposure. Interestingly, the results look somewhat different than for political knowledge. While we again see that the higher emphasis on the harm/care foundation among liberals is only recovered among individuals who are frequent recipients of political news, the reverse is true for the fairness/reciprocity and ingroup/loyalty dimension.

In both cases, the effects of ideology consistent with MFT only appear among individuals who are not frequently exposed to political news. However, only the change in the ideological divide on the harm foundation between high and low level of exposure reaches conventional levels of statistical significance (c.f., Figure D.2). Nevertheless, the result is interesting since it at least tentatively suggests that media consumption can decrease the ideological divide in moral considerations expressed in politics.

Figure 8: Difference between liberals and conservatives in the probability of mentioning each moral foundation (left panel), and in the MFT score given that the foundation was mentioned (right panel), comparing individuals with low and high levels of political discussions while holding all other control variables at their respective means (along with 95% confidence intervals). Positive values indicate that liberals are more likely to mention the respective foundation than conservatives (left panel), or emphasize it more than conservatives (right panel), and vice versa. Estimates are based on separate Tobit models for each foundation's MFT score where ideology is interacted with political discussions. The dimension of purity/sanctity was omitted due to its low general prevalence in individual attitude expressions (c.f., Figure 1).

Lastly, Figure 8 differentiates between individuals who discuss politics more or less frequently. Again, the results are not as straightforward as in the case of political knowledge. There are significant differences in the reliance on the harm/care and fairness/reciprocity dimension between liberals and conservatives who do *not* talk about politics with their peers, while no statistically significant effects are found among individuals who do discuss poli-

tics frequently. These changes between high and low discussion frequency, however, are not themselves statistically significant (c.f., Figure 9). On the other hand, the ideological divide in the emphasis on the ingroup/loyalty foundation is significantly increased among individuals who discuss politics frequently, such that it is only recovered among respondents who engage in frequent discussions.

These results draw much more nuanced picture of the ideological differences in moral reasoning than previous studies. The patterns are only unequivocally consistent with MFT among politically knowledgeable respondents.⁹ However, the picture is more complicated when looking at the influence of media exposure and political discussions. Exposure to political discourse increases the ideological divide on some dimensions but decreases it on others.

Explaining the patterns in Figure 7 and 8 requires a more in-depth analyses of the content of the media coverage as well as the nature of political discussions. It might be too simplistic to assume that exposure to news media and discussions always exacerbate the ideological divide in moral reasoning. In fact, such a pattern should only occur if liberals and conservatives are exposed to rhetoric that raises the respective moral considerations. For example, if a conservative regularly watches news programs that emphasize moral arguments related to individualizing foundations, we would not expect him or her to be *less* likely to raise such considerations. In order to investigate this proposition, we make use of the fact that the 2012 ANES included items indicating whether individuals regularly watched a large array of news outlets. For all media sources available, we downloaded the content of the coverage on either Presidential candidates during the last month of the campaign (October 2012) from Lexis-Nexis and coded their emphasis on moral foundations using the same approach as for open-ended survey responses.¹⁰

⁹This is especially noteworthy given that many studies on MFT are based on opt-in samples collected through www.yourmorals.org, which potentially leads to biases towards higher education among respondents.

¹⁰See appendix C for a more detailed description. In total, we retrieved the content of 28 media sources, such as the New York Times (print and online), CNN.com, or various Fox News Programs. Figure C.1 in the Appendix provides an overview of the media outlets and their respective MFT scores for each dimension.

Figure 9: Content Analysis of Media Sources

Based on the coded content for each media source, we analyze whether individuals who rely on media sources that emphasize a specific foundation more strongly were also more likely to mention the respective moral dimension in their open-ended responses. The results are presented in Figure 9. For each moral foundation, the independent variable consists of a dummy indicating whether the majority of media outlets used regularly by a respondent put a higher emphasis on the moral dimension than other sources (determined by a median split in MFT scores). Note that the analyses therefore only incorporate the moral content of each media source rather than its respective ideological leaning or the respondent's ideology. The dependent variable is again the MFT score for each respective foundation. We can observe that individuals who are mostly exposed to media sources that discuss moral considerations of harm/care and fairness/reciprocity put a stronger emphasis on related moral arguments in their open-ended responses describing their political attitudes. Media exposure therefore induces moral reasoning consistent with the source's content.

As such, we would only expect media exposure to fosters the ideological divide in moral reasoning to the extent that the content of media sources exacerbates the respective patterns. This finding is quite encouraging given that [Haidt \(2012\)](#) prominently argued that incompatibility in moral foundations are an important source for disagreements in politics. The results presented here suggest that differences in moral reasoning can be overcome if individ-

uals are exposed to similar rhetoric in political discourse. While there is no data available to examine the same argument for the case of political discussion, we view the preliminary results presented above as a strong case for subsequent investigations that incorporate the content of political discourse in the analysis of moral reasoning.

Overall, we can conclude from the analyses that whether researchers are able to recover systematic ideological differences in moral reasoning consistent with MFT is conditional on individual-level factors. Political knowledge, media exposure and discussion frequency not only affect general levels of moral reasoning but also moderate the ideological gap between liberals and conservatives. Some portion of the ideological differences in emphasis on moral foundations can therefore be described as a product of learning in the political environment. However, the nature of the relationship between political context and individual moral reasoning is complex and requires further investigation.

Examining Alternative Explanations

One of the greatest concerns for the analyses is whether the open-ended measure captures the theoretical concept of interest. It might be the fact that the ideological divide observed throughout the analyses does not necessarily reflect differences in expressed moral foundations. Rather, the terms in the dictionary may coincidentally recover unrelated differences in word choice between liberals and conservatives when discussing their attitudes towards parties and candidates in the 2012 US Presidential election. For example, one important issue in the election was the Affordable Care Act, which might increase the likelihood of Democrats mentioning the term “care” and thereby increasing the emphasis on the harm/care foundation irrespective of underlying moral considerations.

In order to address this concern, we replicated the main analysis using a different survey that varies the political context as well as the specific set of open-ended survey questions. It was conducted via telephone with 594 adults aged 18 or older between early January,

2001 and July, 2003. The telephone numbers were a random-digit-dial (RDD) sample drawn from residents within a 25 mile radius of a large state university. As such, the survey was conducted during a time without a major Presidential election campaign. Rather than asking about attitudes towards presidential candidates and both major parties, respondents were asked to describe liberals and conservatives (as well as their respective beliefs) in their own words. As such, respondents are not asked to discuss specific political actors in a campaign, but rather describe their views on liberals and conservatives as social groups. The coding and analyses are equivalent to those for Figure 2, although the survey did not contain the Wordsum scores (and varying survey mode) included as controls in the main analyses. The results are displayed in Figure 10.

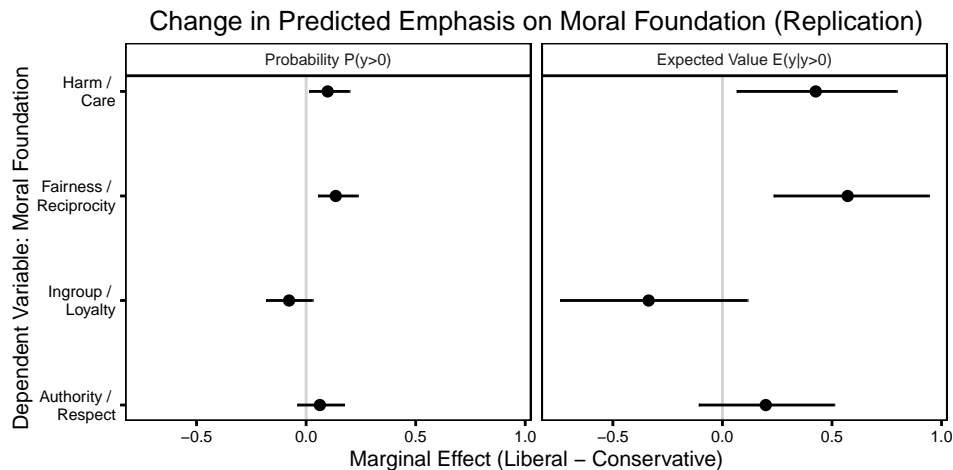

Figure 10: Replication of main model using Long Island Survey Data

The pattern is strikingly consistent with our previous results. While the result for the ingroup/loyalty dimension does not reach conventional levels of statistical significance, we find that liberals are more likely to emphasize the foundations of harm/care and fairness/reciprocity. Additional analyses reveal that the ideological differences are mostly due to the fact that individuals who identify as liberals emphasize the foundations of harm/care and fairness/reciprocity more strongly than conservatives when describing their ingroup (i.e., other liberals and their beliefs), while conservatives emphasize the foundation of ingroup/loyalty more strongly than liberals when describing their ingroup (results available

upon request). The fact that we can recover the same basic ideological pattern in a survey that was conducted in a different political context (i.e., no Presidential campaign), and that relied on a different set of open-ended survey questions (asking about liberals and conservatives and their respective belief), provides further credence for the argument that the dictionary allows us to recover basic moral considerations in political reasoning .

Conclusion

There is much more to be learned about the relationship between moral foundations and broader political attitudes and ideology (e.g., [Feldman, 2013](#)). To fully understand how political views are rooted in morality, researchers need to take a closer look at the conditions under which citizens express moral considerations in the context of politics. In contrast to previous accounts of MFT, we argue that the reliance on moral reasoning is moderated by political knowledge, media exposure, and political discussions. Not every individual necessarily thinks about politics in terms of morality. Rooting political preferences in deeper moral foundations requires exposure to a political discourse that fosters such a connection (c.f., [Clifford, Jerit, Rainey, and Motyl, 2015](#)).

This study utilized open-ended survey responses to investigate the conditionality of MFT in political reasoning. The analyses of open-ended survey responses is valuable in this context because it allows us to evaluate whether citizens make references to moral considerations in a political context that does not induce an explicit connection to morality. As such, we can directly investigate when and how ideological differences in the emphasis of moral foundations manifest themselves in individual reasoning about political actors. More generally, open-ended survey responses provide a promising and still largely neglected data source to investigate the determinants and structure of ideology and political reasoning. In particular, scholars can directly assess moral reasoning in surveys that do not contain the MFQ or related measures, simply by relying on open-ended survey responses. More broadly, fo-

cusing on open-ended measures provides new opportunities to study the role of morality in day-to-day political reasoning, discussions, and social influence.

The empirical analyses presented here extend and qualify previous research on moral foundations and ideology. We found systematic patterns in the emphasis on moral considerations among liberals and conservatives consistent with MFT for three out of four foundations. Liberals are more likely to mention considerations related to harm/care and fairness/reciprocity when discussing their political preferences, whereas conservatives are more likely to emphasize the moral foundation of ingroup/loyalty. The second part of the analyses focused on the political relevance of moral reasoning as conceptualized by open-ended survey responses. Here, the results revealed consistent relationships between individual moral foundations and political preferences or voting behavior, which showed that moral reasoning (measured via open-ended survey responses) is a politically meaningful and influential concept. Lastly, political knowledge and exposure to political discourse increase the reliance on moral considerations. The evidence suggests that moral reasoning in political judgment is conditional on multiple individual-level factors and therefore likely to be part of a broader political learning process. At least in some cases, this learning process appears to imply an increased differentiation between liberals and conservatives in terms of the focus on specific foundations as described by MFT.

Moral foundations can provide a powerful source of structure in political belief systems. However, we cannot assume that the link between morality and politics is homogeneous across individuals and contexts. The present study therefore reaffirms the importance of moral reasoning in politics but highlights its conditionality. The results clarify instances when moral foundations are indeed influential in shaping ideological differences. Individual-level factors such as political knowledge, media exposure, and discussion frequency determine whether and how liberals and conservatives evoke moral considerations in political judgment. Ultimately, a deeper understanding of their influence necessitates further analyses of the broader political context that shapes individual information environments. As such, future

research could examine how the endorsement of moral foundations varies over time and across campaigns. Such an investigation would allow us to further illuminate how exposure to political discourse fosters ideological differences in moral reasoning. A better understanding of the antecedents of this ideological divide is especially important in times of growing partisan polarization.

Appendix D Additional Model Results and Robustness Checks

Figure D.1: Change in predicted overall reliance on moral foundations depending on previous turnout and non-conventional forms of participation (protest, petitions, campaign buttons, letter to congressmen/senator). The plot shows differences in predicted probabilities of mentioning any moral foundation (left panel) as well as in the summed MFT scores given that any foundation was mentioned (right panel), if a respondent engaged in the respective form of participation (vs. not) holding all other variables constant at their respective means (along with 95% confidence intervals). Positive values indicate higher probability of mentioning, or stronger emphasis on moral foundations. Estimates are based on Tobit models and gray triangles indicate estimates while additionally controlling for the remaining variables presented in the figure.

Figure D.2: Change in effect of ideology on emphasis of each moral foundation moderated by political knowledge, media exposure, and frequency of political discussions (difference-in-difference). The plot shows how the difference between liberals and conservatives in predicted probabilities to mention each moral foundation, as well as the respective MFT scores, change if each of the independent variables is increased from its minimum to its maximum value holding control variables constant at their respective means (along with 95% confidence intervals). Positive values indicate that liberals are more likely to mention a specific moral foundation if they score high on the moderating variable (knowledge, exposure, discussions, previous turnout, protest behavior), and vice versa. Estimates are based on individual Tobit models for each foundation and gray triangles indicate estimates while controlling for all remaining variables displayed in the figure.
